Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å; R factor = 0.024; wR factor = 0.065; data-to-parameter ratio = 20.3.

The title zinc complex, $[\text{ZnCl}_2(\text{C}_{18}\text{H}_{22}\text{N}_4)]$, contains a bidentate 1,2-bis(3,5-dimethyl-1*H*-pyrazol-1-ylmethyl)benzene ligand that binds to the zinc atom, forming a nine-membered metallocyclic ring. The geometry about the Zn atom is distorted tetrahedral, with the largest deviation observed in the magnitude of the Cl—Zn—Cl angle. Similar distortions are observed in the cobalt analogue and related zinc compounds containing metallocyclic rings with more than six members. The copper analogue exhibits a more severe distortion of the metal coordination sphere than is observed in the title compound.

Related literature

For the coordination modes of poly(pyrazol-1-ylmethyl)benzene see: Hartshorn & Steel (1995, 1997, 1998); Guerrero *et al.* (2002). For 1,2-bis(3,5-dimethyl-1*H*-pyrazol-1-ylmethyl)benzene complexes with palladium in square-planar coordination, see: Motsoane *et al.* (2007). For the cobalt and copper analogues, see: Chang *et al.* (1994). Discussion of the effect of the size of metallocyclic rings on the distortion of tetrahedral dipyrazole dizinc complexes can be found in Guzei *et al.* (2011). Related structures were found in the Cambridge Structural Database (Allen, 2002). Bond lengths and angles were confirmed to be typical by a *Mogul* structural check (Bruno *et al.*, 2002).

{1,2-Bis[(3,5-dimethyl-1*H*-pyrazol-1-yl- κ N²)methyl]benzene}dichloridozinc(II)

I. A. Guzei, L. C. Spencer, A. Budhai and J. Darkwa

Comment

Poly(pyrazol-1-ylmethyl)benzene exhibits several coordination modes depending on the positions of the pyrazolyl unit on the benzene ring (Hartshorn & Steel, 1995, 1997, 1998; Guerrero *et al.* 2002). There are two types of coordination for the 1,2-bis(pyrazol-1-ylmethyl)benzene analogue. For square planar complexes 1,2-bis(pyrazol-1-ylmethyl)benzene behaves as a monodentate ligand as observed for palladium (Motsoane *et al.*, 2007), whereas for tetrahedral complexes the ligand is bidentate binding to the metal center through nitrogen atoms on each of the pyrazole groups.

In the title complex (**I**) the bis-pyrazolyl ligand binds to the zinc center to form a nine-membered metallocycle. The dependence of the magnitude of the N—Zn—N angle on the size of the metallocycle was discussed by Guzei *et al.* (2011) for 2-(3,5-dimethyl-pyrazol-1-yl)-ethylamine zinc(II) chloride (**II**). In (**I**) the N—Zn—N angle (111.72 (4)°) is much closer to the ideal tetrahedral value because the size of the ring (nine atoms) exceeds 6, whereas in (**II**) the metallocycle is six-membered and more sterically constrained, which leads to a smaller angle of 96.88 (6)°. The Zn center in (**I**) possesses a distorted tetrahedral geometry; the dihedral angle between the planes defined by atoms Zn1, N1, N4 and Zn1, Cl1, Cl2 spans 85.91 (3)°, which is in good agreement with the corresponding angle of 86.77 (4)° in (**II**). The geometrical distortion of the Zn coordination sphere can be compared to those in the Co and Cu analogues ((**III**) and (**IV**), Chang *et al.*, 1994). The Cu analogue is substantially more distorted as revealed by the following values of the Cl—M—Cl angle, N—M—N angle, and a range of the N—M—Cl angles. These values for (**I**), (**III**) and (**IV**), correspondingly are 115.538 (13), 111.72 (4), 103.37 (3)–115.14 (3)°; 115.50 (3), 110.62 (8), 102.56 (6)–112.71 (6)°; 133.4 (7), 141 (7), 95.01 (13)–100.68 (12)°. It is noteworthy that the overall molecular geometry of (**I**) approximately conforms to C₂-symmetry, whereas geometries of (**III**) and (**IV**) are essentially C_s-symmetrical.

The distortion in (**I**) is noticeably smaller than in relevant compounds in the Cambridge Structural Database (Allen, 2002; Guzei *et al.* 2011). A structural check of (**I**) in *Mogul* confirmed its other geometrical parameters to be typical (Bruno *et al.* 2002).

Experimental

A mixture of solid 1,2-bis(pyrazol-1-ylmethyl)benzene (0.27 g, 0.92 mmol) and anhydrous ZnCl₂ (0.120 g, 0.92 mmol) was dissolved in methanol (20 ml), and the resulting solution stirred at room temperature for 12 h. The solvent was removed *in vacuo* and the residue recrystallized from dichloromethane and hexane. Yield: 0.25 g (64%).

Refinement

All H-atoms attached to carbon atoms were placed in idealized locations and refined as riding with appropriate thermal displacement coefficients $U_{\text{iso}}(\text{H}) = 1.5$ times $U_{\text{eq}}(\text{bearing atom})$ for methyl H atoms and $U_{\text{iso}}(\text{H}) = 1.2$ times $U_{\text{eq}}(\text{bearing$

supplementary materials

atom) for all other H atoms. Default effective $X-H$ distances for $T = -173.0^\circ\text{C}$ $C(sp^3)-2H=0.99$, $C(sp^3)-3H=0.98$, $C(sp^2)-H=0.95$.

Figures

Fig. 1. Molecular structure of (I) (Brandenburg, 1999). The thermal ellipsoids are shown at 50% probability level. All hydrogen atoms were omitted for clarity.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
